今日工作内容

1. 修改在线服务日志扫描的逻辑，之前是直接扫描的trpc-go-yaml和trpc-python-yaml，但是实际上启动配置文件名称可能有很多种的；

修改方案：通过api接口读取正式服的所有配置（不一定是启动配置），然后再对每个配置里的内容进行解析，如果其结构能解析为如下结构体，那么就一定是启动配置文件：

```
1      Global struct {
2          Namespace string `yaml:"namespace"`
3      } `yaml:"global"`
4      Server struct {
5          Service []struct{} `yaml:"service"`
6      } `yaml:"server"`
7  }
```

相应新增的代码逻辑如下：

```
1 // GetReleaseConfigName 获取指定gdp服务的正式服服务的所有配置名称
   ConfigName
2 func GetReleaseConfigNames(apiAddr string, projectName string, service string)
   []string {
3     var configNames []string
4     page := 1
5     for {
6         apiURL :=
fmt.Sprintf("%s/v1/project/%s/paas/%s/configs/startup/configs?searchKey=&pag
eNow=%d&pageSize=10",
7         apiAddr, projectName, service, page)
8         headers := getAuthHeaders(apiAddr)
9         req, _ := http.NewRequest("GET", apiURL, nil)
10        for k, v := range headers {
11            req.Header.Add(k, v)
12        }
13        resp, err := http.DefaultClient.Do(req)
14        if err != nil {
15            log.Errorf("request failed: %v", err)
16            break
17        }
18        defer resp.Body.Close()
19        body, _ := io.ReadAll(resp.Body)
20        var result map[string]interface{}
21        if err := json.Unmarshal(body, &result); err != nil {
22            break
23        }
24        if code, ok := result["code"].(float64); !ok || int(code) != 0 {
25            break
26        }
27        data, _ := result["data"].(map[string]interface{})
28        dataList, _ := data["dataList"].([]interface{})
29        if len(dataList) == 0 || dataList == nil {
```

2. 为思航哥他们提供hok中所有正式服服务的启动配置文件；

```
1 func main() {
2     configDir := "hokconfigs/"
3     services := task.ListAllServices(apiHOKAddr, projectHOKName)
4     for _, service := range services {
5         serviceName := service["paas_name"].(string)
6         // 获取该服务所有正式配置名称
7         serviceConfigName := task.GetReleaseConfigNames(apiHOKAddr,
projectHOKName, serviceName)
8         for _, configName := range serviceConfigName {
9             // 获取该配置名称的所有生效版本
10            configVersions := task.GetStartupConfigList(apiHOKAddr,
projectHOKName, serviceName, configName)
11            for _, config := range configVersions {
12                // 获取该版本的具体配置
13                version := config["version"].(string)
14                data := task.SearchOneStartupConfig(apiHOKAddr,
projectHOKName, serviceName, version)
15                var parsedConfig ConfigNameConfig
16                if err := yaml.Unmarshal([]byte(data), &parsedConfig); err != nil {
17                    log.Errorf("yaml unmarshal failed: %v", err)
18                } else {
19                    log.Infof("Namespace: %v", parsedConfig.Global.Namespace)
20                    if parsedConfig.Global.Namespace != "" &&
parsedConfig.Server.Service != nil {
21                        safeFileName := serviceName + "_" + configName + "_"
+ version + ".yaml"
22                        filePath := filepath.Join(configDir, safeFileName)
23                        if err := os.WriteFile(filePath, []byte(data), 0644); err != nil
{
24                            log.Errorf("write file failed %s: %v", filePath, err)
25                        } else {
26                            log.Infof("write file success: %s", filePath)
27                        }

```
